RE: Addendum
Subsurface Investigation (Roadway & Bridge) for
Underpass of CSX Railroad Connecting Commerce Parkway and KY 146
Oldham County, Kentucky
Item #5-434.00
DLZ Project No. 0631-0006.02

Mr. Silliman:

The above-referenced project consists of lowering the existing Allen Lane at the CSX railroad crossing, and relocating the existing Allen Lane to provide a grade separation at the Allen Lane/CSX railroad intersection. A new CSX bridge will also be constructed over the lowered Allen Lane, and a temporary railroad diversion track (railroad runaround) will be installed north of the existing track to maintain railroad traffic during the Allen Lane/CSX railroad construction. The findings of the subsurface exploration performed in 2014 and associated recommendations were presented in the Report of Subsurface Investigation (Roadway) for Underpass of CSX Railroad Connecting Commerce Parkway and KY 146, Oldham County, Kentucky, dated September 4, 2015 and the Report of Subsurface Investigation (Bridge) for Underpass of CSX Railroad Connecting Commerce Parkway and KY 146, Oldham County, Kentucky, dated September 4, 2015. To finalize the design of the project, an additional geotechnical exploration was performed in 2024 at the proposed CSX railroad runaround to evaluate the stability of the proposed railroad embankment as well as to address the review comments on both September 2015 reports. This letter report includes the findings of the additional geotechnical exploration along with associated engineering analyses recommended in the review comments. The geotechnical exploration has been performed essentially in accordance with DLZ's proposal dated May 23, 2024. A summary of the general scope of work as indicated in the proposal is as follows:

- Perform a total of ten borings, B-03 through B-12, along the proposed runaround alignment.
- Perform dynamic cone penetration tests at boring locations B-01, B-02, B-13, and B-14.
- Perform a boring B-32C with rock coring at Station 1528+55 of the proposed railroad bridge (near Pier 1) to an elevation of approximately 805 to confirm the bedrock type and quality for the drilled shaft support of the proposed railroad bridge.
- Install an observation well at each of boring B-5 and B-12 locations.

1950 Haggard Ct., Lexington, KY 40505 | OFFICE 859.299.5226 | ONLINE WWW.DLZ.COM

- Perform slope stability, settlement, and bearing capacity analyses for railroad runaround Stations 1518+00, 1528+00, and 1538+00.
- Perform a stability analysis at CSXT Mainline Station 1526+00 where the existing railroad embankment is widening and will have a proposed embankment height of 28 feet. The subsurface conditions at a previous boring B-22 drilled in 2014 is used for the analysis.

FIELD EXPLORATION

DLZ prepared the scope of field exploration based on the proposed work of the additional exploration. The field exploration plan was reviewed and subsequently approved by the Kentucky Transportation Cabinet (KYTC) Geotechnical Branch.

The field exploration originally consisted of drilling elevation borings (B-03 through B-12 and B-32C), performing five dynamic cone penetration (DCP) tests at borings B-01, B-02, B-04, B-13, and B-14), and installing two observation wells at borings B-5 and B-12. Originally, DCP tests were planned at four boring locations (B-01, B-02, B-13, and B-14). Because of the site constraints, boring B-04 could not be drilled at the originally planned location at the toe of the existing railroad embankment. A DCP test was performed instead at the originally planned location of B-04 and boring B-04 was drilled offset approximately 35 feet north of its original location. During the field exploration, some of the borings were also drilled offset from the originally planned boring locations to accommodate the site conditions. The field exploration were performed between November 11 and 15, 2024. The borings were drilled using an all-terrain-vehicle (ATV) mounted rotary-type drill rig, which had hammer calibrated on June 13, 2023 (hammer efficiency of 74.7 percent). A drawing showing the as-drilled boring locations with respect to the existing features is presented in Appendix I. The stations and offsets and latitude and longitudes of the as-drilled boring locations are on the boring logs in Appendix I. The as-drilled locations and elevations of the borings were determined in the field by representatives of DLZ, except that the boring stake for B-11 could not be located at the time of survey, and the ground surface elevation at boring B-11 was estimated based on Google Earth imagery.

Standard Penetration Tests were performed generally in 1.5-foot increments at intervals not exceeding 5 feet through the overburden to the top of bedrock. A Shelby tube sample was collected from each of borings B-03, B-05, and B-7. Five feet of rock cores were obtained from borings B-05, B-8, and B-12 and 32 feet of rock cores from boring B-32C. NQ size diamond coring tools were used with water as the circulating fluid. All drilling and sampling were performed in general accordance with the current KYTC Geotechnical Manual, Section GT-300. Information concerning the general drilling procedures is presented in Appendix I.

The present field investigation was undertaken to develop engineering information to meet the purposes as described above. The intent of these services was not to uncover or identify any contaminated subsurface material that may contain hazardous or flammable substances. Identification of such substances requires specialized exploration techniques and analyses that were not employed in this investigation.

A field log was prepared for each boring. These logs contain visual classifications of the materials encountered during drilling as well as an interpolation of the subsurface conditions between samples. Final logs, included in Appendix I, represent our interpretation of the field logs and may include modifications based on laboratory observations and tests of the field samples. The final logs describe the materials encountered, their thicknesses, and the locations where samples were obtained. Ground surface elevations at the borings are presented on the final logs.

GENERALIZED SURFACE CONDITIONS

The following sections present the generalized subsurface conditions encountered by borings B-03 through B-12 drilling along the proposed railroad runaround location. For more detailed information, please refer to the boring logs presented in the Appendix I. Please note that the strata contact lines shown on the boring logs represent approximate boundaries between soil and rock layers. In the field, the actual transitions between soil and bedrock layers might be different both vertically and laterally.

Generally, the subsurface conditions encountered in the borings drilled in this additional field exploration are similar to those encountered in the borings previously drilled for the project.

Surface Material

The surface materials encountered in borings B-03 through B-11 generally consisted of 3 to 9 inches of topsoil. No topsoil was reported in boring B-12.

Fill

Fill soils consisting of silty sand and low plasticity lean clay with cinders/slag were encountered at depths of between 0.5 and 13.5 feet in boring B-03.

Lean Clays and Fat Clays

Beneath the ground surface, fill soils or topsoil, the overburden soils consisted mostly of low to high plasticity clays with isolated layers of silty sands. The top of bedrock was encountered at depths varying from 0.3 to 18.5 feet below the existing ground surface. The upper portion of the clay soils occasionally contained trace organics. Fat clays (AASHTO A-7-6) were encountered in five (B-03, B-05, B-07, B-08, and B-09) of the ten borings drilled. Hand penetrometer strength test values in the clay soils generally varied from 1.0 to 4.5+ tons per square foot (tsf), indicating medium stiff to hard consistency.

Auger Refusal

Auger refusal, indicative of top of bedded material, was encountered in all of the borings at depths ranging from 0.0 (ground surface) to 18.5 feet below the existing ground surface (i.e., elevations ranging from 868.7 to

831.8 feet). While the depths to the auger refusal conditions varied across the site, the top of rock elevations generally increased from the west to the east along the railway runaround alignment.

Bedrock

Rock coring was performed in borings B-05, B-08, B-10, and B-12. The rock core samples generally consisted of a Rock Disintegration Zone (RDZ) and very fine to fine grained, brown and gray dolomite. Rock recovery ranged between 90 and 96 percent and the Rock Quality Designation (RQD) values were mostly greater than 50 percent, ranging between 54 and 78 percent, which corresponds to a Rock Quality Description of fair to good according to Table 39 of FHWA-IF-02-034 *Geotechnical Engineering Circular No. 5 Evaluation of Soil and Rock Properties*. The RQD value of the rock core obtained from boring B-08 was 14, which corresponds to a Rock Quality Description of very poor according to Table 39 of FHWA-IF-02-034.

Observation Wells and Groundwater Levels

During the field exploration, immediate groundwater levels were reported in some of the borings. Observation wells were installed in borings B-05 and B-12. The following table, Table 1, presents the elevations where groundwater was encountered during drilling (immediate water level) and where the groundwater level was encountered after the completion of drilling. Boring locations without reported groundwater levels are not included in the table below except for B-12 where an observation well was installed at the boring location.

Table 1 – Groundwater Observations Summary

Boring Location	Depth (Elevation) to Immediate Water Level, ft ¹	Static Water Depth (Elevation), ft	In Observation Well, Depth/Elevation, ft (Date Measured) ³	Depth (Elevation) to Bedrock, ft
B-03 (850.5)	3.5 (847.0)	NR ¹	N/A ²	18.5 (832.0)
B-05 (848.8)	NR ¹	NR ¹	14.0/834.8 (01-22-2025)	17.0 (831.8)
B-07 (851.4)	13.5 (837.9)	NR ¹	N/A ⁴	18.5 (832.9)
B-08 (856.4)	13.5 (842.9)	NR ¹	N/A ⁴	13.5 (842.9)
B-09 (860.8)	13.7 (847.1)	NR ¹	N/A ⁴	13.5 (847.3)
B-10 (864.7)	8.0 (856.7)	NR ¹	N/A ⁴	8.5 (856.2)
B-12 (868.5)	NR ²	NR ¹	NR ¹	0.0 (868.5)

¹NR: Measured, but none reported.

²N/A: No observation well was installed.

³Measured from the ground surface.

It should be noted that groundwater levels may fluctuate with seasonal variations and following periods of heavy or prolonged precipitation and, therefore, the readings indicated on the boring logs may not be representative of the long-term groundwater level. Long-term monitoring would be needed to obtain a more accurate estimate of the groundwater table elevation. Consequently, during construction or at other times during the project life, water levels may be higher or lower than observed at the time of this investigation.

LABORATORY TESTING AND RESULTS

Laboratory tests were performed in accordance with applicable AASHTO or Kentucky Methods of soil and rock testing specifications (KM) as specified in the KYTC Geotechnical Guidance Manual, dated June 2005. Where both AASHTO and KM standards are designated in the guidance manual, the KM procedure was used. The results of the laboratory tests are shown on a laboratory test summary tables in Appendix II and on the appropriate soil profile sheets in Appendix IV.

The laboratory testing program consisted of visual classifications of all collected soil and decomposed rock samples, and soil classification tests on selected Standard Penetration Test samples. The types of soils resulting from laboratory classification testing were primarily either lean clay (CL or A-6, A-7-6) or fat clay (CH or A-7-6), which is in general agreement with the results of visual classification of all collected soil. The in-place moisture contents of tested samples varied approximately from 3 to 59 percent with an average of approximately 21 percent.

RESULTS OF DYNAMIC CONE PENETRATION TESTS

Dynamic cone penetration (DCP) tests were performed between the existing railroad tracks at boring locations B-01, B-02, B-13, and B-14 to determine the materials of the existing embankment. High blows per 6 inches of penetration (ranging from 15 to over 50 blows) and refusal were generally encountered at depths of less than four feet below the top of the existing railroad embankment, indicating hard or very dense materials immediately below the embankment crest. Based on the conversations between field personnel from DLZ and CSX, the upper 6 feet of the existing railroad embankment generally consisted of granular material (stone), which is consistent with the results of the DCP tests at the boring locations B-01, B-02, B-13, and B-14.

ENGINEERING ANALYSES

For this additional geotechnical exploration, the following engineering analyses were performed:

- Slope stability, settlement, and bearing capacity analyses for railroad runaround Stations 1518+00, 1528+00, and 1538+00.
- Stability analysis at CSXT Mainline Station 1526+00 where the existing railroad embankment is widening and will have a proposed embankment height of 28 feet. The subsurface conditions at a previous boring B-22 is used for the analysis.

The cross-sections of each station analyzed along with the results of the analyses are included in the Appendix III.

Soil and Rock Parameter Selections

The subsurface profile for the analyses used the stratigraphy disclosed by the borings and material properties were estimated from normalized Standard Penetration Test blow counts (N_{60} -values), visual classification, index properties, unconfined compressive strengths, and engineering judgment. The federal government's Naval Facilities Design Manual (NAVFAC DM-7.2) and the FHWA's Soils and Foundations Workshop Manual were used as guide in estimating the soil and rock parameters used for the analyses. Additional published engineering literatures were also used, wherever applicable, to provide additional references for the soil and rock parameters. Generally, the subsurface conditions encountered in the borings drilled in this additional field exploration are similar to those encountered in the borings previously drilled for the project. Consequently, the soil and rock parameters used in the above-mentioned 2015 report were used for the present engineering

analyses. The soil and rock properties used for the stability analyses are included with the analysis output appended to this letter report.

The soil and rock profiles used for the engineering analyses are the subsurface conditions encountered in the boring(s) near the section/station analyzed; hence, boring B-03 for Station 1518+00, boring B-07 for Station 1528+00, boring B-12 for Station 1538+00, and previous boring B-22 drilled in 2014 for Station 1526+00. In the analyses, the groundwater level was assumed to be 2 feet above the soil-rock interface where groundwater was not encountered in the boring used for the analysis. A vertical live load surcharge of 1,880 psf (distributed over a standard length of a railroad tie, 8'-6") was used based on the recommendation indicated in the appendix of the "CSXT Public Project Information", last revised on August 10, 2012. This vertical railroad surcharge was applied in the stability analysis for both short-term (undrained) and long-term (drained) conditions.

Given the results of the DCP tests and the conversations between field personnel from DLZ and CSX, the upper 6 feet of the existing railroad embankment was assumed to be granular material. Beneath the granular embankment fill, cohesive embankment fill was assumed in the stability analyses. As recommended by American Railway Engineering and Maintenance-of-Way Association (AREMA) Manual for Railway Engineering, Chapter 1, Part 1.3.7.5.6, granular new fill was also assumed to be used in the upper 6 feet of the new embankment area to minimize slope stability concerns associated with drainage issue immediately beneath the railroad tracks. In the analyses, a friction angle of 34° was used for the granular embankment fill in reference to Tables 8-20-0 and 8-20-3 of the AREMA manual (medium clean sand) and Table 10.4.6.2.4-1 of the AASHTO 9th Edition.

Slope Stability Analyses

The global stability analyses were performed for the above-mentioned stations, considering the short term, long-term as well as near term conditions, where applicable. The short term analyses considered undrained shear strength parameters; whereas long-term analyses considered drained shear strength parameters. The global slope stability analyses were performed utilizing limit equilibrium methodology (Spencer method of slices) with the computer program SLIDE 2D v9, by Rocscience, assuming potential circular failure surfaces. Furthermore, it was assumed that potential failure surfaces did not extend below the bottom of the rock disintegration zone, if applicable, or top of bedrock. The following table, Tables 2, summarizes the results of the stability analyses.

Table 2 - Summary of Summary of Embankment Stability Analyses (Railroad Runaround)

Station	F.S./Target F.S. Short-term (Undrained)	F.S./Target F.S. Intermediate- term	Long-term (Drained)
1518+00	1.4 (new granular fill)/ 1.1-1.3	1.9 (existing granular fill)/ ***	1.3 (new granular fill)/1.4-1.6 1.4 (new granular fill with 5' undercut)/1.4-1.6
1526+00	1.8 (new granular fill)/ 1.1-1.3	1.8 (existing granular fill)/ ***	1.3 (new granular fill)/1.4-1.6 1.5 (new granular fill with NO RR surcharge)/1.4-1.6
1528+00	2.3 (new granular fill)/ 1.1-1.3 2.6 (new cohesive fill)/ 1.1-1.3	-- ¹	1.5 (new granular fill)/1.4-1.6 1.5 (new cohesive fill)/1.4-1.6
1538+00	2.1 (new cohesive fill)/ 1.1-1.3 2.1 (new granular fill)/ 1.1-1.3	-- ¹	1.8 (new cohesive fill)/ 1.4-1.6 1.8 (new granular fill)/ 1.4-1.6

¹Not needed.

Settlement Analyses

Based on the anticipated amounts of new embankment fill shown in the cross-section of each station analyzed, the settlement analyses were performed in general accordance with the FHWA's Soils and Foundation Workshop Manual (NHI-00-045, July 2000). The following table, Tables 3, summarizes the results of the settlement analyses.

Table 3 - Summary of Results of Settlement Analyses

Station	Settlement, inch
1518+00	0.9 (no undercut) 0.1 (5' undercut) ¹
1528+00	1.3 (no undercut) 1.0 (5' undercut) ¹
1538+00	-- ²

¹Five feet of undercut is necessary to meet the required target factor of safety for stability (see Table 2 above).

²New embankment height is less than 5 feet and the embankment is founded on RDZ.

Bearing Capacity of the Runaround Railroad Embankment

FHWA guidelines suggest that if the pressure exerted by the weight of the embankment exceeds three times the undrained shear strength of the foundation soils, the potential for lateral squeeze exists. Based on the cross-section of the proposed embankment fill at Station 1528+00, the new embankment will be approximately 8.6 feet high with side slopes of 2H:1V. Boring B-07 is located near the new embankment and encountered very stiff to hard fat clay in the upper portion of the foundations soils. In the analysis, an undrained shear strength of 1,000 psf was used for the existing very stiff to hard clay and a unit weight of 130 pcf for the new embankment fill. Using the FHWA guidelines, the pressure increases applied by the new fill are less than three times the undrained shear strength of the foundation soils, indicative of unlikeliness of lateral squeeze.

Evaluations of bearing capacity for the railroad track foundations were performed in general accordance with AASHTO LRFD Bridge Design Specifications 9th Edition, Section 10.6.3.1.2c “Considerations for Footings on Slopes”. The following table, Table 4, summarizes the results of the bearing capacity evaluations.

Table 4 - Summary of Results of Bearing Capacity Evaluations

Station	Estimated Factored Bearing Resistance, psf	Railrod Surcharge, psf
1518+00	11,790 (new granular fill)	3,760 (two tracks)
1528+00	3,550 (new cohesive fill) 5,700 (new granular fill)	1,880
1538+00	3,780 (new cohesive fill) 7,640 (new granular fill)	1,880

ADDITIONAL BORING AT THE PROPOSED BRIDGE LOCATION

Boring B-32C was drilled approximately at Station 1528+55 of the proposed railroad bridge (near Pier 1). The boring encountered dolomite rock fragments at a depth of approximately 18.5 feet (elevation 838.4). Rock coring began at the depth of 20 feet (elevation 836.9) and was terminated at the depth of 52 feet (elevation 804.9). The rock cores consisted primarily of dolomite. Shale (claystone) was embedded with the dolomite at depths of between 47 feet (elevation 809.9) and 49.3 (elevation 49.3). A log of the boring is included with this report in Appendix I.

GENERAL INFORMATION DRILLING PROCEDURES AND LOGS OF BORINGS

Drilling and sampling were conducted in accordance with procedures generally recognized and accepted as standardized methods of investigation of subsurface conditions concerning geotechnical engineering considerations. Borings were drilled with either a truck-mounted or ATV-mounted drill rig.

Drive split-barrel sampling was performed in 1.5 foot increments at intervals not exceeding 5 feet. In the event the sampler encountered resistance to penetration of 6 inches or less after 50 blows of the drop hammer, the sampling increment was discontinued. Standard penetration data were recorded and one or more representative samples were preserved from each sampling increment.

In borings where rock was cored, NXM or NQ size diamond coring tools were used.

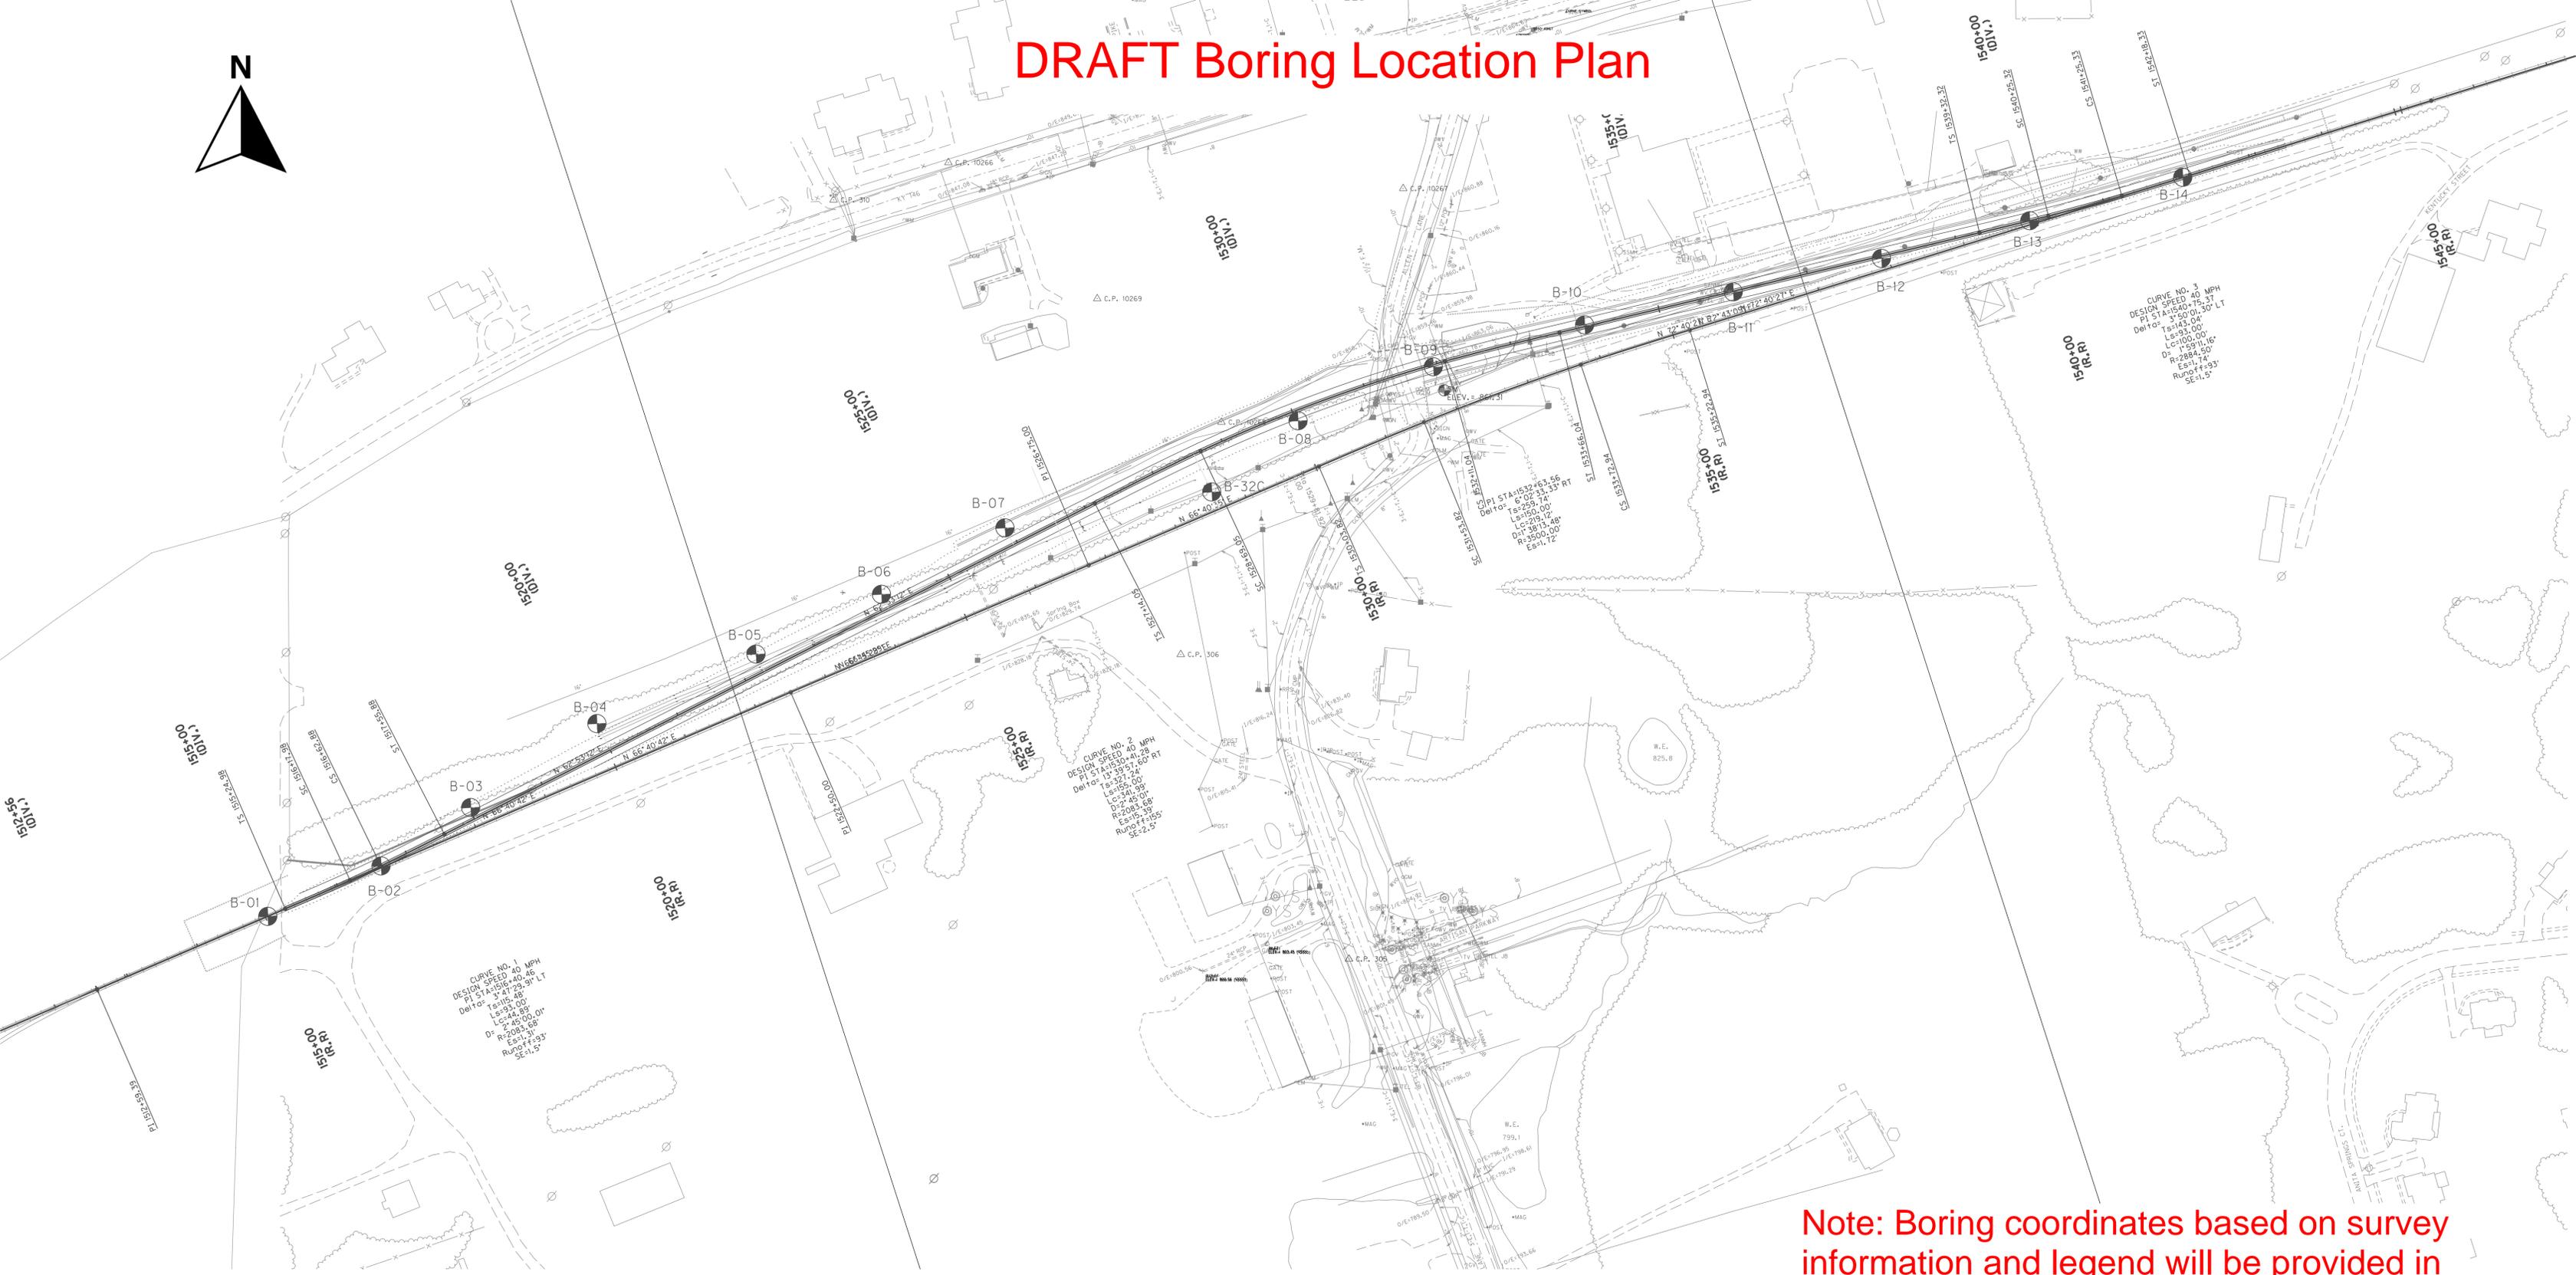

In the laboratory all samples were visually classified by a geotechnical engineer. Moisture contents of representative fine-grained soil samples were determined. A limited number of samples, considered representative of foundation materials present, were selected for performance of grain-size analyses and plasticity characteristics tests. The results of these tests are shown on the boring logs.

The boring logs included in the Appendix have been prepared on the basis of the field record of drilling and sampling, and the results of the laboratory examination and testing of samples. Stratification lines on the boring logs indicating changes in soil stratigraphy represent depths of changes approximated by the driller, by sampling effort and recovery, and by laboratory test results. Actual depths to changes may differ somewhat from the estimated depths, or transitions may occur gradually and not be sharply defined. The boring logs presented in this report therefore contain both factual and interpretative information and are not an exact copy of the field log.

Although it is considered that the borings have disclosed information generally representative of site conditions, it should be expected that between borings conditions may occur which are not precisely represented by any one of the borings. Soil deposition processes and natural geologic forces are such that soil and rock types and conditions may change in short vertical intervals and horizontal distances.

Soil/rock samples will be stored at our laboratory for a period of six months. After this period of time, they will be discarded, unless notified to the contrary by the client.
