1 INTRODUCTION

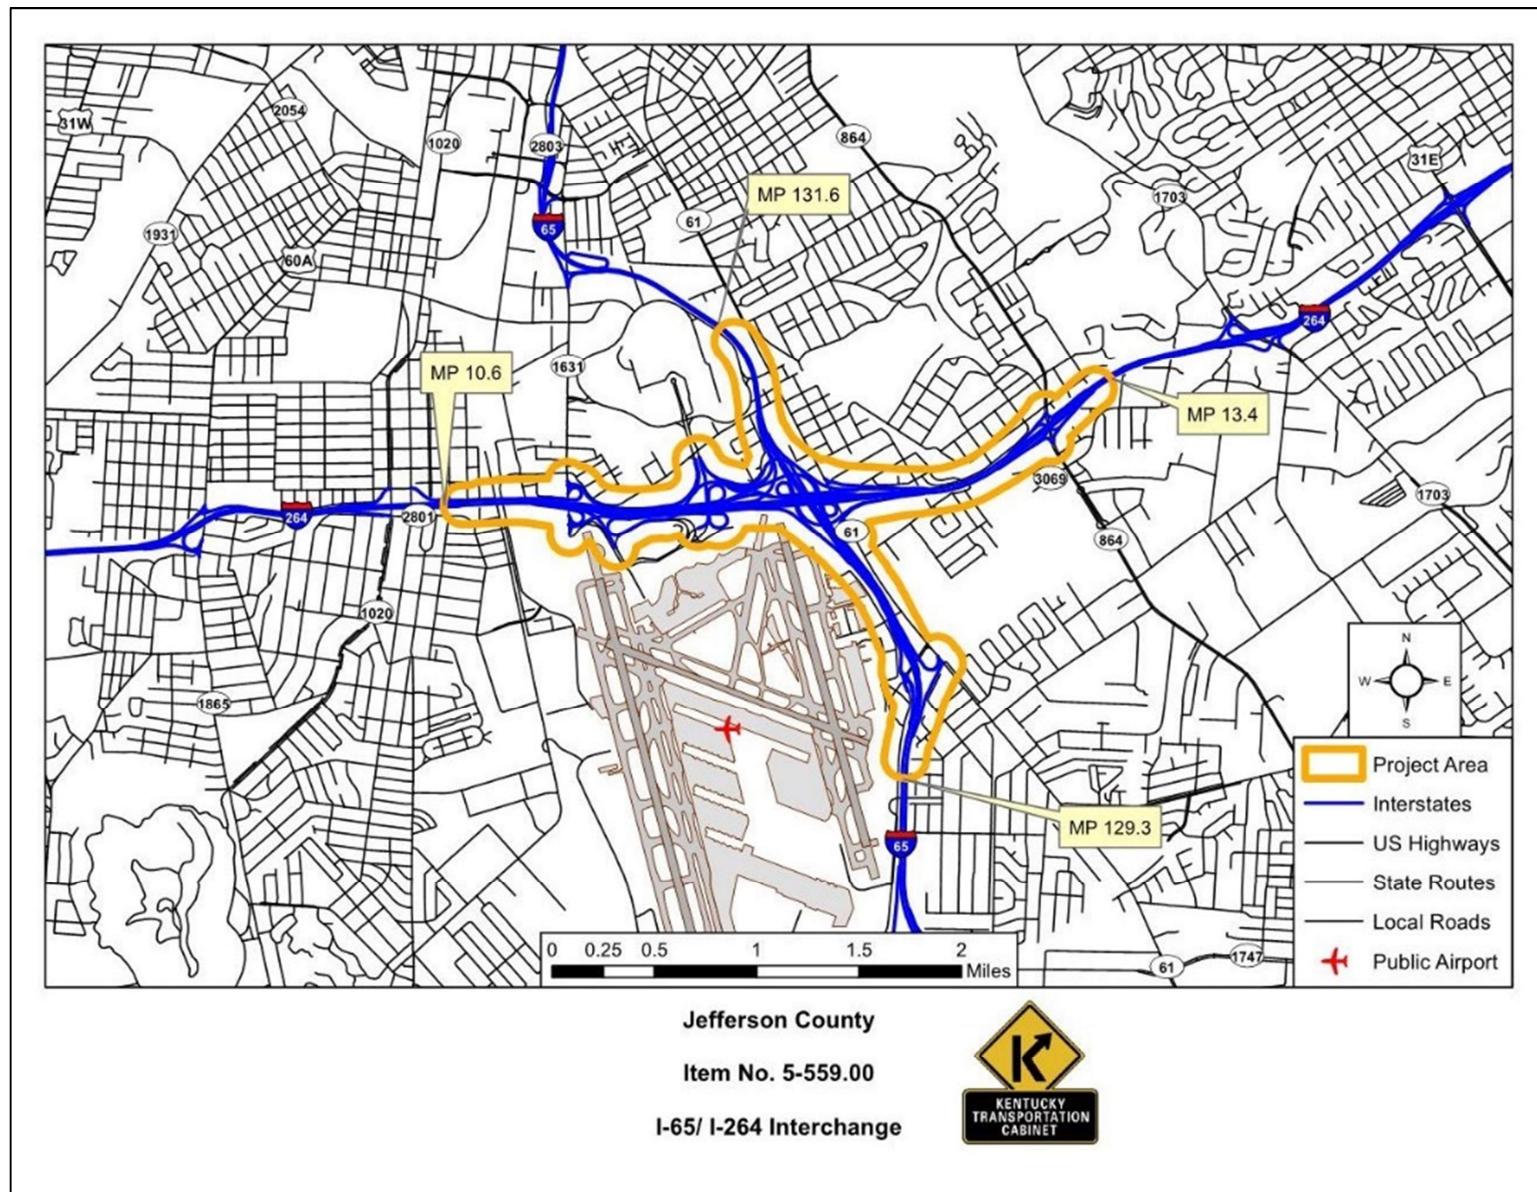

WSP was contracted by the Kentucky Transportation Cabinet (KYTC) to perform a study to identify safety and congestion improvements along the I-65/I-264 Interchange in Louisville, Kentucky. The study area encompasses I-65 from MP 129.3 to MP 131.6 and I-264 from MP 10.6 to MP 13.4. The study includes identifying short-term and long-term improvements that KYTC may use for further project development implementation. As part of this study, a traffic forecast was performed to aid in the evaluation of future no-build conditions and alternative improvement projects. The base year used for traffic volumes was 2020, with a 2045 future design year. The following report explains the methodology of the development of existing study area volume flows and origin-destinations (OD), as well as the growth rate and future OD development.

1.1 STUDY AREA

The study area boundary includes I-65 (MP 129.3 to MP 131.6) and I-264 (MP 10.6 to MP 13.4). **Figure 1** shows the study area. The project study area includes the following areas:

- Crittenden Drive directly adjacent to the exit ramps from I-264
- Entrances and exits from the Louisville International Airport
- Phillips Lane at Freedom Way
- Preston Highway directly adjacent to the exit ramps from I-264 and I-65
- Poplar Level Road directly adjacent to the exit ramps from I-264
- Grade Lane directly adjacent to the exit ramps from I-65

Figure 1: Study Area

2 DATA COLLECTION

WSP collected traffic counts from KYTC count stations as well as turning movement and ramp counts performed by Cummins Consulting Services (CCS) using Miovision Datalink. The counts are provided in **Appendix A**. Streetlight data was purchased to complement the traffic count data and ensure accurate travel patterns between study area origins and destinations. Processed Streetlight Data is shown in **Appendix B**.

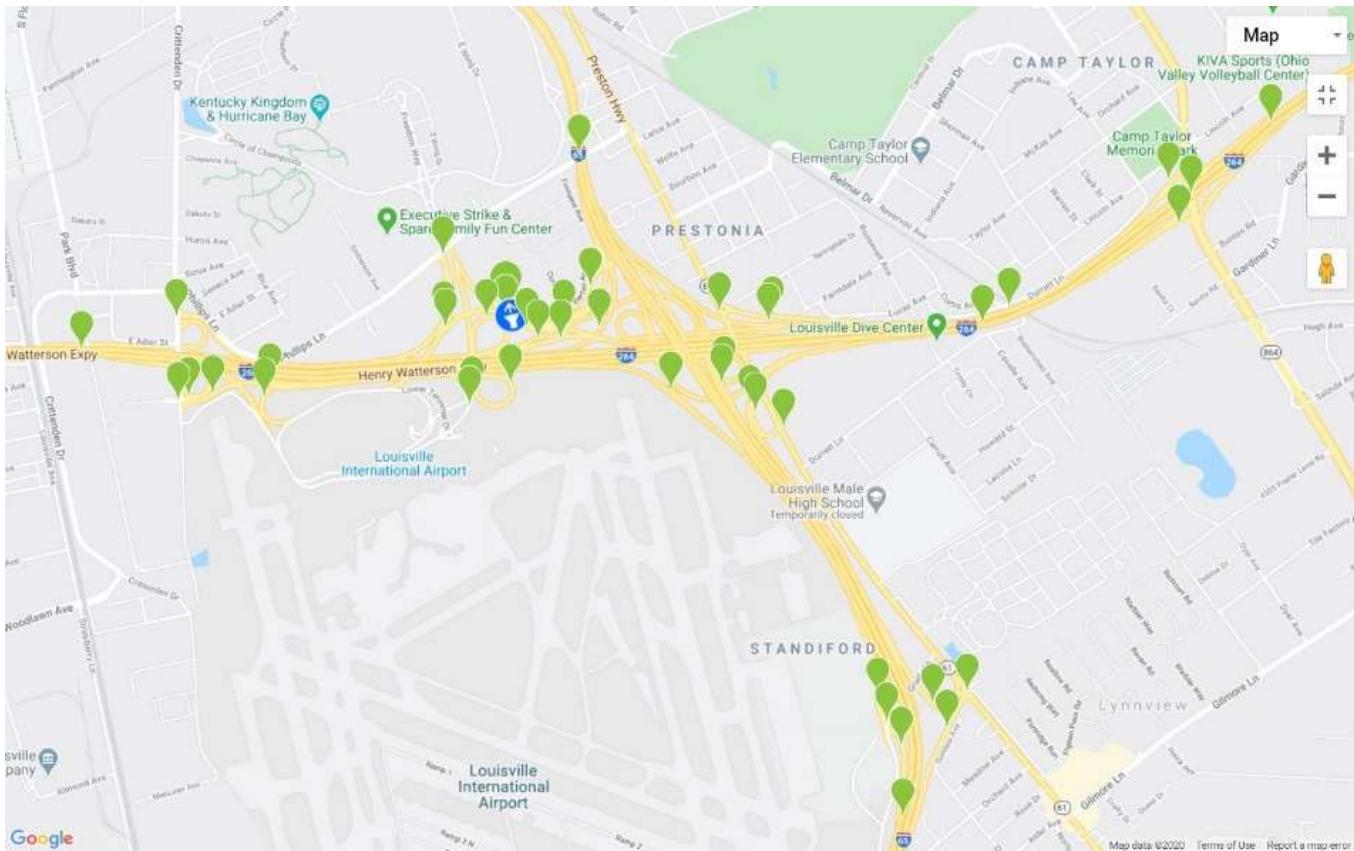

2.1 TRAFFIC COUNTS

Traffic counts were collected between 2:00 PM and 8:00 PM on a Friday. Many crashes occur on Fridays, so Friday was chosen as it represents a typical worst-case scenario for traffic volumes and safety. Vehicle counts were collected by class. Counts were collected before and after the peak hour to evaluate the network through the greatest levels of congestion and back into Free Flow conditions. Traffic counts were organized into 30-minute bins and by class. After raw counts were accounted for at each segment and turning movement, volumes were balanced in each 30-minute bin. Further discussion on this is found in Section 3. The peak hour was determined to be from 4:00 PM to 5:00 PM.

The Miovision count locations are shown in **Figure 2**. These counts were collected from 2:00 PM to 8:00 PM and classified into lights, buses, and trucks. Miovision counts consist of a combination of mainline, ramp, and turning movement counts.

KYTC count stations were used as a reasonableness check to compare to the Miovision counts. Where count stations were available, they were used to determine the percentage of total daily traffic that occurred between 2:00 PM and 8:00 PM. That factor was applied to the Miovision counts to calculate Average Daily Traffic (ADT) on each segment. Diagrams showing the KYTC count locations and percentage of the ADT that occurs between 2:00 and 8:00 PM are shown in **Appendix C**. These percentages were applied to the CCS counts. Final ADTs are shown in **Appendix D**.

Figure 2: Count Station Locations – Crittenden Area

2.2 STREETLIGHT DATA

WSP used Streetlight Data to form OD pairs through the study area. Streetlight Data tracks vehicles from point to point over time to track route usage in an area. The user determines each entry/exit point, defining the desired study area. After processing the data collected by Streetlight, OD pair percentages are formed for each hour observed. **Table 1** shows an example of the OD percentages calculated from the Streetlight Data.

3 BALANCING FLOWS

After the previously described data processing was completed, a balancing of flows was needed between all segments and turning movements. Volumes were balanced in 30-minute bins for light vehicles, trucks, and buses. If traffic counts between segments were within reason of the previous and subsequent segments, counts were assumed to be accurate. Whenever segment counts were considered inaccurate, further investigation was performed to determine the cause. The modeling team found a few locations with technical errors occurring, such as cameras counting vehicles in multiple lanes when it shouldn't or incorrectly attributing turning movements. WSP patched volumes and counted vehicles on some videos to obtain more accurate results. Some segments did not have video collecting data on them, as the span of the study area and the number of branching routes is extensive. If traffic counts were not collected on a segment, then natural volume balancing was done from the segments before and after the uncounted segment. **Figure 3** shows an example section of the flow map for the 3:00-3:30 PM time period for the light vehicle class. Counts that are shown in blue denote segments with a Miovision traffic count, green denotes segments without a count that were calculated based on segments before or after, and yellow counts were manually adjusted a small amount to balance turning movement approach totals with the turning movements. **Appendix E** shows the full 30-minute bins of balanced flows for each vehicle type, as well as the total flow. The 2020 peak hour volume line diagram is shown in **Appendix F**.

Figure 3: 3:00 PM Balanced Light Vehicles

4 ORIGIN-DESTINATION MATRIX DEVELOPMENT

The Origin-Destination matrices were developed using the 30-minute balanced flows and the OD distribution from Streetlight Data. For each of the five 30-minute intervals and for each vehicle class analysed (lights, trucks, and buses), the origin volumes from the balanced flow maps were held constant and were multiplied by the Streetlight Data destination percentages for each respective origin. These preliminary matrices were adjusted when needed to match all ramp volumes along the interchange based on the vehicle routes between an origin and a destination. This two-step process ensured that the Streetlight Data would be consistent with the counts performed for this project. **Figure 4** shows the OD matrix for light vehicles during the 4:00-4:30 PM interval. The developed matrices contained the volumes between each origin and each destination and were the VISSIM volume inputs for the dynamic traffic assignment model. **Appendix G** contains each OD matrix organized by 30-minute bin and vehicle type.

Figure 4: 4:00-4:30 PM Light Vehicles OD Matrix

5 GROWTH RATE

5.1 KIPDA MODEL

The Kentuckiana Regional Planning and Development Agency (KIPDA) travel demand model was used to evaluate the study area and calculate a growth rate. Volumes from the KIPDA 2020 and 2040 models were used to establish the growth rates at study area origins and destinations. **Tables 2** and **3** show the volumes and percent growth at each study area origin and destination. After discussions between WSP and KIPDA, it was determined that the best approach is to apply one general growth rate across the study area. Several reasons for this exist, including: the dense level of the existing development, the significant change over the previous 20 years for various reasons suggests the same could happen over the next 20 years, as well as the vast outliers in some locations, such as Crittenden Drive, that are not believed to decrease by 27% over 20 years. Thus, a low, yet positive growth rate of 4.2% over 20 years, or 0.21% growth per year, was determined to be appropriate. **Appendix H** provides 2045 ADT and peak hour volumes in the network.

Table 2: KIPDA Origin Traffic Growth Rates

ORIGINS	2020 VOLUMES	2040 VOLUMES	% CHANGE

Total	435986	454299	4.2%

6 FUTURE OD MATRIX

The KIPDA model only forecasts to the year 2040, however, the future design year for this project is 2045. Therefore, the 0.21% growth rate was applied to the study area OD matrices over 25 years, to produce future 2045 OD matrices. These are included in **Appendix I**. The 2045 OD matrices were used as the inputs for the VISSIM dynamic assignment traffic model for future Build and No-Build scenarios.
